Sufficient Statistics for Economic Mobility: When Do Measures Agree?

Rory McGee
UWO

October 2026

Chicago Fed: Labor Supply, Consumption and Family Dynamics Conference

Has U.S. Intergenerational Mobility Declined?

- Researchers measure economic mobility
  - ... in many outcomes (e.g., incomes, wealth, education, health, ...)
  - ... for many uses (e.g., normative analysis, policy evaluation, validating models, ...)
  - ... for many comparisons (e.g., cross-country, regions, history, ...)

Has U.S. Intergenerational Mobility Declined?

- Researchers measure economic mobility
  - ... in many outcomes (e.g., incomes, wealth, education, health, ...)
  - ... for many uses (e.g., normative analysis, policy evaluation, validating models, ...)
  - ... for many comparisons (e.g., cross-country, regions, history, ...)
- ... **and in many ways**: intergenerational elasticity (IGE), rank-rank slopes, transition matrices, directional mobility, axiomatic indices (e.g., Shorrocks)

Has U.S. Intergenerational Mobility Declined?

- Researchers measure economic mobility
  - ... in many outcomes (e.g., incomes, wealth, education, health, ...)
  - ... for many uses (e.g., normative analysis, policy evaluation, validating models, ...)
  - ... for many comparisons (e.g., cross-country, regions, history, ...)
- ... **and in many ways**: intergenerational elasticity (IGE), rank-rank slopes, transition matrices, directional mobility, axiomatic indices (e.g., Shorrocks)
- Different measures often produce consistent rankings of mobility
  (e.g., Katz and Krueger 2017, Berman 2022, Deutscher and Mazumder 2023)

Has U.S. Intergenerational Mobility Declined?

- Researchers measure economic mobility

  ... in many outcomes (e.g., incomes, wealth, education, health, …)

  ... for many uses (e.g., normative analysis, policy evaluation, validating models, …)

  ... for many comparisons (e.g., cross-country, regions, history, …)

- … **and in many ways**: intergenerational elasticity (IGE), rank-rank slopes, transition matrices, directional mobility, axiomatic indices (e.g., Shorrocks)

- Different measures often produce consistent rankings of mobility
  (e.g., Katz and Krueger 2017, Berman 2022, Deutscher and Mazumder 2023)

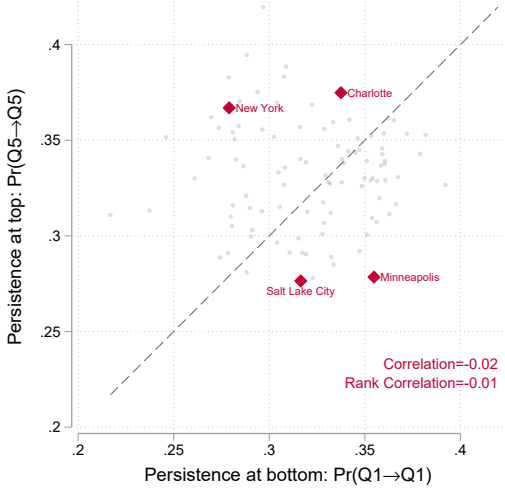

- But not always

  ... U.S. over time (mid-century births: sharp ↓ Davis & Mazumder 2024 vs. modest to flat Jácome, Kuziemko & Naidu 2025)

  ... across places (Chetty et al., 2014)

Even Positional Mobility Measures Disagree

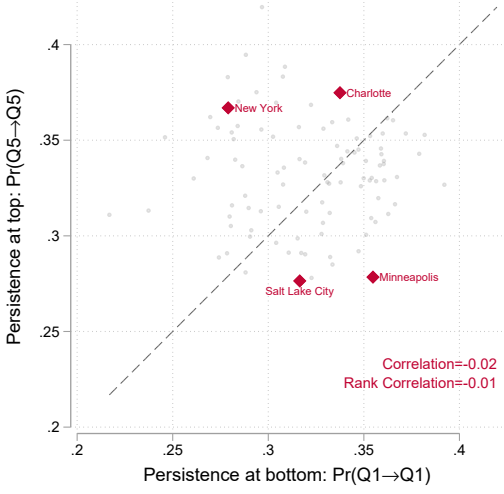

Persistence across the 100 largest commuting zones (Chetty et al., 2014)

Even Positional Mobility Measures Disagree

Persistence across the 100 largest commuting zones (Chetty et al., 2014)

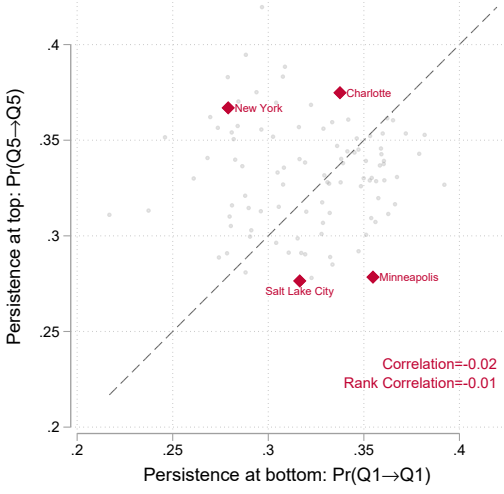

- Bottom (Q1→Q1) vs. top (Q5→Q5) persistence:
  ⟶ disagree for **half** of CZ pairs

Even Positional Mobility Measures Disagree

Persistence across the 100 largest commuting zones (Chetty et al., 2014)

- Bottom (Q1→Q1) vs. top (Q5→Q5) persistence:
  ⟶ disagree for **half** of CZ pairs
- Salt Lake vs. NYC?
  ⟶ depends on which tail you use

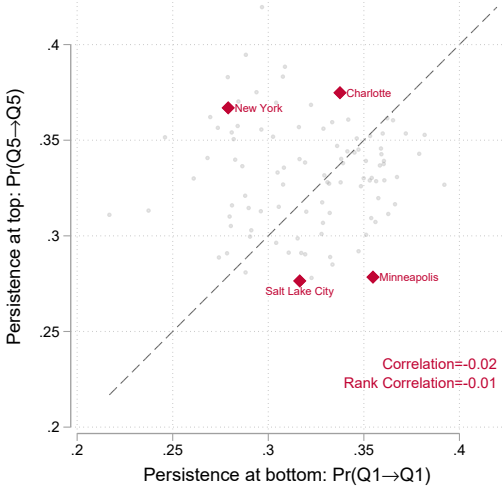

Even Positional Mobility Measures Disagree

Persistence across the 100 largest commuting zones (Chetty et al., 2014)

- Bottom (Q1→Q1) vs. top (Q5→Q5) persistence:
  ⟶ disagree for **half** of CZ pairs
- Salt Lake vs. NYC?
  ⟶ depends on which tail you use

Two fundamental questions:

1. When *should* we expect measures to agree?
2. What does disagreement *tell us*?

This Paper Provides Answers

1. Agreement of measures depends on single property of parent-child joint distribution
   - Concordance order: parent-child ranks are *everywhere* more aligned
   - If economies ranked by concordance, *all* standard measures agree
     $\longrightarrow$ measures as ordinal substitutes (for transition probabilities, *only* then)

This Paper Provides Answers

1. Agreement of measures depends on single property of parent-child joint distribution
   - Concordance order: parent-child ranks are *everywhere* more aligned
   - If economies ranked by concordance, *all* standard measures agree
     $\longrightarrow$ measures as ordinal substitutes (for transition probabilities, *only* then)
2. Disagreement reflects
   i. different weightings over regions of the joint distribution
   ii. different sensitivity to changing shape (any measure = rank-dependence + distributions)

This Paper Provides Answers

1. Agreement of measures depends on single property of parent-child joint distribution
   - Concordance order: parent-child ranks are *everywhere* more aligned
   - If economies ranked by concordance, *all* standard measures agree
     $\longrightarrow$ measures as ordinal substitutes (for transition probabilities, *only* then)
2. Disagreement reflects
   i. different weightings over regions of the joint distribution
   ii. different sensitivity to changing shape (any measure = rank-dependence + distributions)
3. Concordance depends on who gains skill, not how much (Becker-Tomes-Loury)
   - Raising every child's skills can leave mobility untouched

This Paper Provides Answers

1. Agreement of measures depends on single property of parent-child joint distribution
   - Concordance order: parent-child ranks are *everywhere* more aligned
   - If economies ranked by concordance, *all* standard measures agree
     $\longrightarrow$ measures as ordinal substitutes (for transition probabilities, *only* then)
2. Disagreement reflects
   i. different weightings over regions of the joint distribution
   ii. different sensitivity to changing shape (any measure = rank-dependence + distributions)
3. Concordance depends on who gains skill, not how much (Becker-Tomes-Loury)
   - Raising every child's skills can leave mobility untouched

$\longrightarrow$ **Lorenz dominance for mobility**: unifies measures + necessity + failures + economics
((Atkinson; Tchen; D'Agostino & Dardanoni)

Setup

Copulas and Concordance: Visual Intuition ▸ Example II

Sklar (1959): $F(Y^K, Y^P) = C\big(F_K(Y^K), F_P(Y^P)\big)$ Incomes (Y^K, Y^P), C = joint dist. of ranks

- Copula encodes *all* rank-dependence $\perp\!\!\!\perp$ of income distributions ▸ Mass points

  $\longrightarrow$ positional measures are different summaries of the same copula

Copulas and Concordance: Visual Intuition ▸ Example II

Sklar (1959): $F(Y^K, Y^P) = C\big(F_K(Y^K), F_P(Y^P)\big)$ Incomes (Y^K, Y^P), C = joint dist. of ranks

- Copula encodes *all* rank-dependence $\perp\!\!\!\perp$ of income distributions ▸ Mass points

  $\longrightarrow$ positional measures are different summaries of the same copula

Child's Quintile

Increasing Concordance

Copulas and Concordance: Visual Intuition ▸ Example II

Sklar (1959): $F(Y^K, Y^P) = C\big(F_K(Y^K), F_P(Y^P)\big)$ Incomes (Y^K, Y^P), C = joint dist. of ranks

- Copula encodes *all* rank-dependence $\perp\!\!\!\perp$ of income distributions ▸ Mass points

  $\longrightarrow$ positional measures are different summaries of the same copula

- Shift mass from off-diagonal (origin independent) to diagonal (rank-preserving) cells

- Elementary exchange $\approx$ Pigou-Dalton transfer for mobility ▸

The Concordance Order

Definition: (Tchen 1980) Economy A is **more concordant** than economy B ($C^A \succeq C^B$) if:

$$C^A(u, v) \geq C^B(u, v) \quad \forall\, u, v \in [0, 1]$$

The Concordance Order

Definition: (Tchen 1980) Economy A is **more concordant** than economy B ($C^A \succeq C^B$) if:

$$C^A(u, v) \geq C^B(u, v) \quad \forall\, u, v \in [0, 1]$$

- Higher concordance = parent-child ranks more aligned everywhere
  - Stochastic dominance for *dependence* $\longrightarrow$ mobility analogue of Lorenz dominance

The Concordance Order

Definition: (Tchen 1980) Economy A is **more concordant** than economy B ($C^A \succeq C^B$) if:

$$C^A(u, v) \geq C^B(u, v) \quad \forall\, u, v \in [0, 1]$$

- Higher concordance = parent-child ranks more aligned everywhere
  - Stochastic dominance for *dependence* $\longrightarrow$ mobility analogue of Lorenz dominance
  - Incomplete order over distributions, but covers empirically relevant cases jump e.g.

    "intuitive requirement that children from higher-income families are less likely to have lower incomes" (Chetty et al., 2017); "empirically unlikely transition matrices" (Shorrocks, 1978); "all-or-nothing" (Berman, 2022)

The Concordance Order

Definition: (Tchen 1980) Economy A is **more concordant** than economy B ($C^A \succeq C^B$) if:

$$C^A(u, v) \geq C^B(u, v) \quad \forall\, u, v \in [0, 1]$$

- Higher concordance = parent-child ranks more aligned everywhere
  - Stochastic dominance for *dependence* $\longrightarrow$ mobility analogue of Lorenz dominance

    "intuitive requirement that children from higher-income families are less likely to have lower incomes" (Chetty et al., 2017); "empirically unlikely transition matrices" (Shorrocks, 1978); "all-or-nothing" (Berman, 2022)
  - Testable: each (u, v) is a transition probability, $\Pr(R^K \leq u \mid R^P \leq v)$
- Higher concordance $\longleftrightarrow$ **lower mobility**

When Do Measures Agree?

Concordance Orders All Standard Mobility Measures

▸ No time? Skip intuition

Props 1-4: Fix marginals. If $C^A \succeq C^B$, then economy A is *less mobile* than B by:

1. Regression/Correlation-based measures:
   - IGE: $\beta^A \geq \beta^B$, Rank-rank slope: $\rho^A \geq \rho^B$, Intergenerational correlation
2. "Local" measures:
   - Conditional expected rank $\longrightarrow$ rotates around the median (linear fit)
3. Transition probabilities:
   - diagonal $\uparrow$, off-diagonal $\downarrow$ (at every threshold), Directional mobility†
4. Axiomatic measures:
   - Shorrocks trace†, Fields & Ok, D'Agostino & Dardanoni, Cowell & Flachaire

Concordance Orders All Standard Mobility Measures

No time? Skip intuition

Props 1-4: Fix marginals. If $C^A \succeq C^B$, then economy A is *less mobile* than B by:

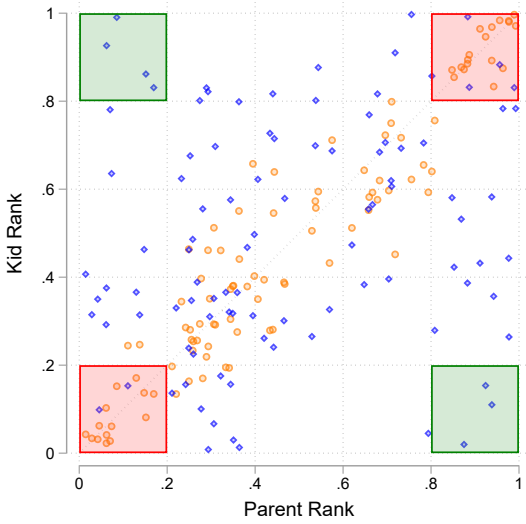

1. Regression/Correlation-based measures:
   - IGE: $\beta^A \geq \beta^B$, Rank-rank slope: $\rho^A \geq \rho^B$, Intergenerational correlation
2. "Local" measures:
   - Conditional expected rank $\longrightarrow$ rotates around the median (linear fit)

4. Axiomatic measures:
   - Shorrocks trace†, Fields & Ok, D'Agostino & Dardanoni, Cowell & Flachaire

$\longrightarrow$ Measures are ordinal substitutes: observe one ranking, know all others

† requires stronger diagonal concentration A1 common proxies & measurement error (Prop. 5) ▸

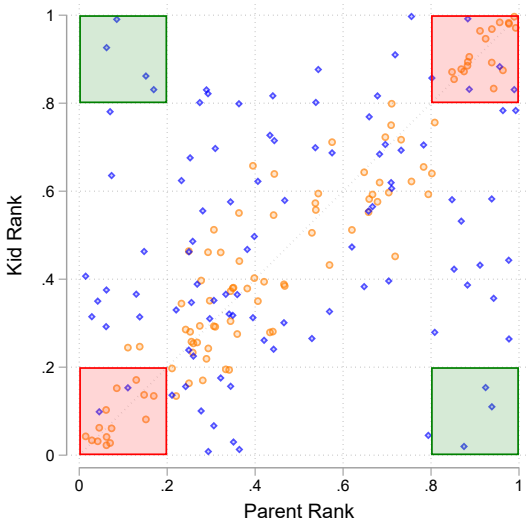

Why Does Concordance Order These Measures?

Transition probability: *one point* of the copula

Why Does Concordance Order These Measures?

Transition probability: *one point* of the copula

Mobility Measure:

$$\Pr(R^K > \tau \mid R^P > \tau) = \frac{1-2\tau+C(\tau,\tau)}{1-\tau}$$ (Q5→Q5: $\tau = 0.8$)

If $C^A \geq C^B$ everywhere

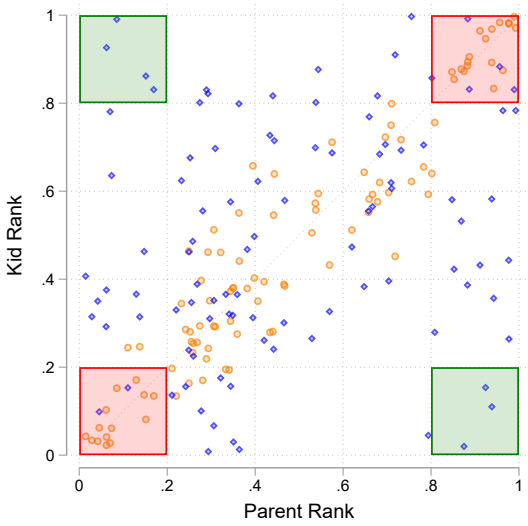

$\longrightarrow C^A(\tau,\tau) \geq C^B(\tau,\tau)$

$\longrightarrow \mathrm{TP}^A \geq \mathrm{TP}^B$

(Copula definition, simplest cases!)

Why Does Concordance Order These Measures?

Transition probability: *one point* of the copula

Mobility Measure:

$$\Pr(R^K > \tau \mid R^P > \tau) = \frac{1-2\tau+C(\tau,\tau)}{1-\tau}$$ (Q5→Q5: $\tau = 0.8$)

If $C^A \geq C^B$ everywhere

$\longrightarrow C^A(\tau,\tau) \geq C^B(\tau,\tau)$

$\longrightarrow \mathrm{TP}^A \geq \mathrm{TP}^B$

(Copula definition, simplest cases!)

Uses C at *one point*

$\longrightarrow$ depends on where you look

When Concordance Fails, Measures Must Disagree

Concordance is a partial order $\longrightarrow$ not all economies are ranked, e.g.

Par. Quintile \ Child's Quintile	1	2	3	4	5
1	0.32	0.24	0.2	0.15	0.08
2	0.25	0.23	0.21	0.18	0.12
3	0.19	0.22	0.22	0.21	0.16
4	0.15	0.18	0.21	0.24	0.22
5	0.09	0.12	0.16	0.22	0.41

No Concordance Order $\longleftrightarrow$

Par. Quintile \ Child's Quintile	1	2	3	4	5
1	0.58	0.00	0.00	0.14	0.28
2	0.00	0.86	0.00	0.00	0.14
3	0.00	0.00	1.00	0.00	0.00
4	0.14	0.00	0.00	0.86	0.00
5	0.28	0.14	0.00	0.00	0.58

- Identical rank correlation (0.32), but different transition probabilities

When Concordance Fails, Measures Must Disagree

- For fixed marginals, any measure:

$$\Delta M = \iint \underbrace{W_M(u,v)}_{\leq 0} \left[C^A(u,v) - C^B(u,v) \right] du\, dv$$

When Concordance Fails, Measures Must Disagree

- For fixed marginals, any measure:

$$\Delta M = \iint \underbrace{W_M(u,v)}_{\leq 0} \Big[C^A(u,v) - C^B(u,v) \Big] \, du \, dv$$

- Measures differ only in their weights:
  - Rank-rank: uniform ($|W_\rho| = 12$) TP: one point IGE: tails ($|W_\beta| \propto 1/f_K f_P$)

When Concordance Fails, Measures Must Disagree

- For fixed marginals, any measure:

$$\Delta M = \iint \underbrace{W_M(u,v)}_{\leq 0} \Big[C^A(u,v) - C^B(u,v) \Big] \, du \, dv$$

- Measures differ only in their weights:
  - Rank-rank: uniform ($|W_\rho| = 12$) TP: one point IGE: tails ($|W_\beta| \propto 1/f_K f_P$)
- Concordance: $C^A - C^B \geq 0$ everywhere $\longrightarrow$ $\Delta M \leq 0$ whatever the weights

When Concordance Fails, Measures Must Disagree

- For fixed marginals, any measure:

$$\Delta M = \iint \underbrace{W_M(u,v)}_{\leq 0} \Big[C^A(u,v) - C^B(u,v) \Big] \, du \, dv$$

- Measures differ only in their weights:
  - Rank-rank: uniform ($|W_\rho| = 12$) TP: one point IGE: tails ($|W_\beta| \propto 1/f_K f_P$)
- Concordance: $C^A - C^B \geq 0$ everywhere $\longrightarrow$ $\Delta M \leq 0$ whatever the weights
- Fails: $C^A - C^B$ changes sign $\longrightarrow$ the weights decide
  - For transition probabilities, disagreement is *guaranteed* (Prop. 3)

$\longrightarrow$ Agreement among a few measures $\neq$ robustness

Decomposition: Positional Dependence vs. Marginals ▸ e.g.

- Comparisons across time/space typically involve different marginal distributions

Decomposition: Positional Dependence vs. Marginals ▸ e.g.

- Comparisons across time/space typically involve different marginal distributions

- Any measure $M = M(C, F_K, F_P)$ can be decomposed:

$$\Delta M = M^B - M^A = \underbrace{M(C^B, F_K^B, F_P^B) - M(C^A, F_K^B, F_P^B)}_{\text{Copula component (varying dependence)}}$$

$$+ \underbrace{M(C^A, F_K^B, F_P^B) - M(C^A, F_K^A, F_P^A)}_{\text{Marginal component (varying marginals)}}$$

Decomposition: Positional Dependence vs. Marginals ▸ e.g.

- Comparisons across time/space typically involve different marginal distributions
- Any measure $M = M(C, F_K, F_P)$ can be decomposed:

$$\Delta M = M^B - M^A = \underbrace{\mathbf{M(C^B, F_K^B, F_P^B) - M(C^A, F_K^B, F_P^B)}}_{\text{Copula component (varying dependence)}}$$

$$+ \underbrace{M(C^A, F_K^B, F_P^B) - M(C^A, F_K^A, F_P^A)}_{\text{Marginal component (varying marginals)}}$$

Decomposition: Positional Dependence vs. Marginals ▸ e.g.

$$+ \underbrace{M(C^A, F_K^B, F_P^B) - M(C^A, F_K^A, F_P^A)}_{\text{Marginal component (varying marginals)}}$$

- Rank-based measures: Marginal component $= 0$ by construction!

Decomposition: Positional Dependence vs. Marginals ▸ e.g.

- Comparisons across time/space typically involve different marginal distributions
- Any measure $M = M(C, F_K, F_P)$ can be decomposed:

$$\Delta M = M^B - M^A = \underbrace{M(C^B, F_K^B, F_P^B) - M(C^A, F_K^B, F_P^B)}_{\text{Copula component (varying dependence)}}$$

$$+ \underbrace{M(C^A, F_K^B, F_P^B) - M(C^A, F_K^A, F_P^A)}_{\text{Marginal component (varying marginals)}}$$

- Rank-based measures: Marginal component $= 0$ by construction!
- Level-based measures (e.g. IGE): Both components non-zero & potentially opposite

  Order matters $\longrightarrow$ average over both orderings (Shapley-Owen-Shorrocks)

What Moves Concordance?

Microfoundation: Becker–Tomes–Loury

- Classic dynastic investment model

$$\max_{I} \; U\Big(\overbrace{Y^P + T(Y^P) - I}^{\text{parent consumption}}\Big) + \delta\, \mathbb{E}_\theta\Big[U\Big(\overbrace{W\big(\underbrace{\theta f(I, Y^P)}_{H^K}\big)}^{Y^K}\Big)\Big]$$

  - Parents choose investment I; T: transfers; f: skill technology
  - W: wage schedule, strictly increasing θ: luck, realised after investment

Microfoundation: Becker–Tomes–Loury

- Classic dynastic investment model

$$\max_{I} \; U\Big(\overbrace{Y^P + T(Y^P) - I}^{\text{parent consumption}}\Big) + \delta\, \mathbb{E}_\theta\Big[U\Big(\overbrace{W\big(\underbrace{\theta f(I, Y^P)}_{H^K}\big)}^{Y^K}\Big)\Big]$$

  - Parents choose investment I; T: transfers; f: skill technology
  - W: wage schedule, strictly increasing θ: luck, realised after investment

- **Skill index** $S(y) = \ln f\big(I^\star(y), y\big) \longrightarrow \ln H^K = S(Y^P) + \ln\theta$
  - Poor child overtakes rich child only if luck exceeds the gap in skill indices

Microfoundation: Becker–Tomes–Loury

- Classic dynastic investment model

$$\max_{I} \; U\Big(\overbrace{Y^P + T(Y^P) - I}^{\text{parent consumption}}\Big) + \delta\, \mathbb{E}_\theta\Big[U\Big(\overbrace{W\big(\underbrace{\theta f(I, Y^P)}_{H^K}\big)}^{Y^K}\Big)\Big]$$

  - Parents choose investment I; T: transfers; f: skill technology
  - W: wage schedule, strictly increasing θ: luck, realised after investment

- **Skill index** $S(y) = \ln f\big(I^\star(y), y\big) \longrightarrow \ln H^K = S(Y^P) + \ln\theta$
  - Poor child overtakes rich child only if luck exceeds the gap in skill indices

- When do changes in technology, preferences, or policy lead to more mobility?

Who Gains Skill, Not How Much

Prop 6: Let incidence $\Delta(y) = S^A(y) - S^B(y)$

$$\Delta \text{ increasing in } y \longrightarrow C^A \succeq C^B$$ (average of Δ irrelevant)

Who Gains Skill, Not How Much

Prop 6: Let incidence $\Delta(y) = S^A(y) - S^B(y)$

$$\Delta \text{ increasing in } y \longrightarrow C^A \succeq C^B \qquad \text{(average of } \Delta \text{ irrelevant)}$$

- Investment ↑ for **every family**: mobility can fall, stay *unchanged*, or *rise* (Cor. 3)
- Return to skill: copula unchanged, IGE scales ⟶ ranks track who gains

Who Gains Skill, Not How Much

Prop 6: Let incidence $\Delta(y) = S^A(y) - S^B(y)$

$$\Delta \text{ increasing in } y \longrightarrow C^A \succeq C^B \qquad \text{(average of } \Delta \text{ irrelevant)}$$

- Investment ↑ for **every family**: mobility can fall, stay *unchanged*, or *rise* (Cor. 3)
- Return to skill: copula unchanged, IGE scales $\longrightarrow$ ranks track who gains
- **Cor. 4:** Both tails gain more than average $\longrightarrow$ copulas cross
  - e.g., targeted programs + elite sorting (as across CZs)

U.S. Mobility in the 20th Century

Has Mobility Increased? Testing the Concordance Order Details

- Replicate Jácome, Kuziemko & Naidu (2025)

  15 pooled surveys; parental income imputed from occupation × race × region; U.S.-born men 30–50; 56,102 father-son pairs

Has Mobility Increased? Testing the Concordance Order Details

- Replicate Jácome, Kuziemko & Naidu (2025)

  15 pooled surveys; parental income imputed from occupation $\times$ race $\times$ region; U.S.-born men 30–50; 56,102 father-son pairs

- Test $C^A \geq C^B$ on a 20×20 grid $\approx$ Kolmogorov-Smirnov test for stochastic dominance

Has Mobility Increased? Testing the Concordance Order Details

- Replicate Jácome, Kuziemko & Naidu (2025)

  15 pooled surveys; parental income imputed from occupation × race × region; U.S.-born men 30–50; 56,102 father-son pairs

- Test $C^A \geq C^B$ on a 20×20 grid $\approx$ Kolmogorov-Smirnov test for stochastic dominance

- Long run vs. 1910s? Increased mobility for every later cohort

Has Mobility Increased? Testing the Concordance Order Details

- Replicate Jácome, Kuziemko & Naidu (2025)

  15 pooled surveys; parental income imputed from occupation × race × region; U.S.-born men 30–50; 56,102 father-son pairs

- Test $C^A \geq C^B$ on a 20×20 grid $\approx$ Kolmogorov-Smirnov test for stochastic dominance

- Long run vs. 1910s? Increased mobility for every later cohort

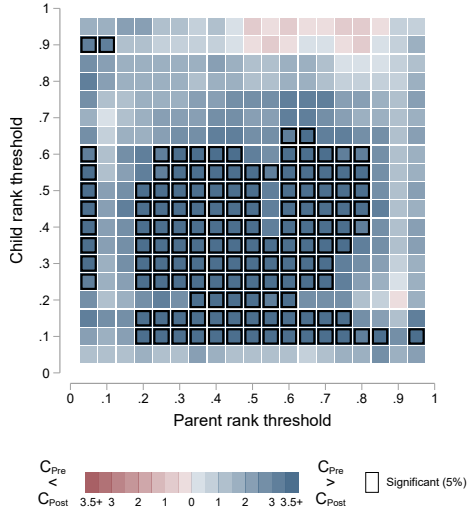

- Successive decades?

Decade A	Decade B	$pval_{A \succeq B}$	$pval_{B \succeq A}$	Interpretation
1920	1930	.469	.178	Indistinguishable
1930	1940	.813	.001	↑ mobility
1940	1950	.001	.262	↓ mobility
1950	1960	.001	.001	Copulas cross
1960	1970	.581	.026	↑ mobility

Long Run: Broad-Based Positional Mobility Gains

1910s vs. 1950s (reject one)

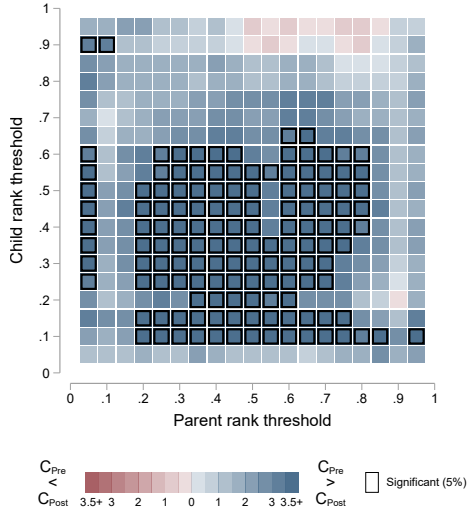

- Each cell: $C^A \lessgtr C^B$
- Blue: later cohort more mobile

Long Run: Broad-Based Positional Mobility Gains

1910s vs. 1950s (reject one)

- Each cell: $C^A \lessgtr C^B$
- Blue: later cohort more mobile
- Broad-based gains

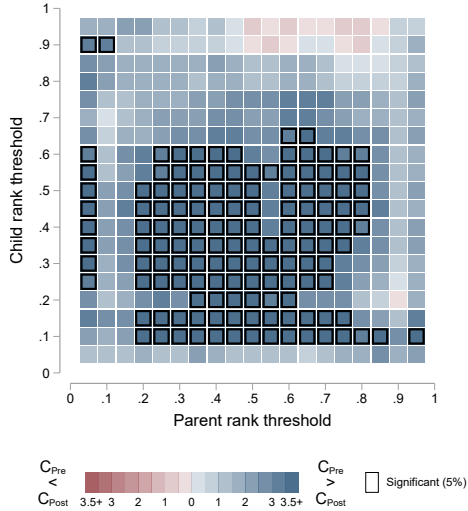

Long Run: Broad-Based Positional Mobility Gains

1910s vs. 1950s (reject one)

- Each cell: $C^A \lessgtr C^B$
- Blue: later cohort more mobile
- Broad-based gains

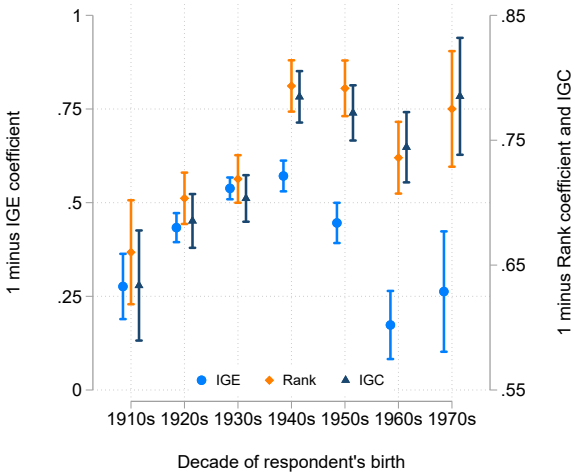

Has U.S. mobility increased?

- Yes! vs Early 20thC
- *Every* rank-based measure
- But not monotone

Long Run: Rank Gains vs. the IGE

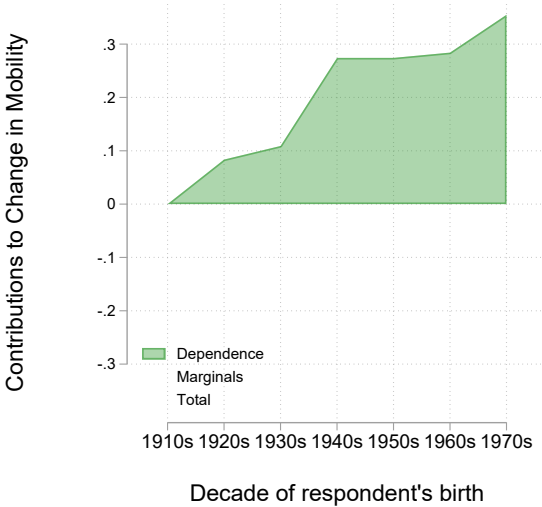

Other Measures

- Rank-rank slope: mobility rises to mid-century, reverses for 1960s
- IGC tracks rank-rank (not generic)
- IGE diverges starting 1950s

Long Run: Rank Gains vs. the IGE

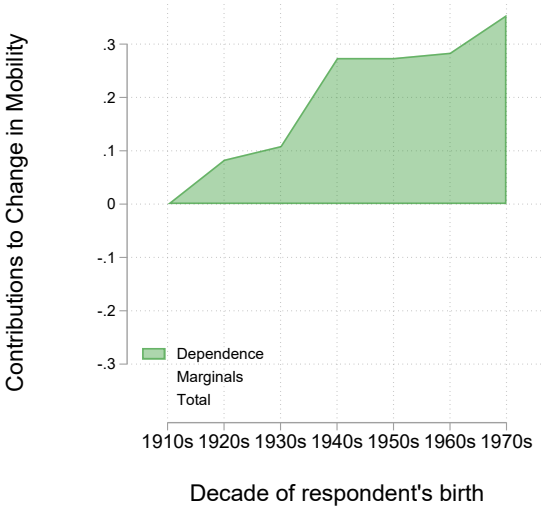

Other Measures

- **Dependence component:** rising mobility + plateau
  - Like the rank-rank slope

Long Run: Rank Gains vs. the IGE

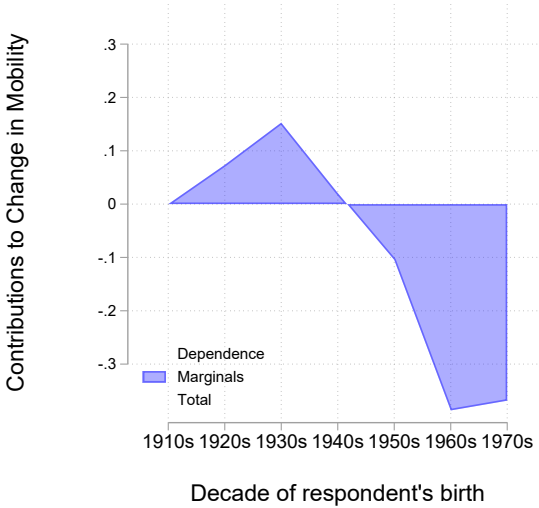

Other Measures

- **Dependence component:** rising mobility + plateau
  - Like the rank-rank slope
  - IGE and rank-rank still disagree for 1950s $\rightarrow$ 1960s

Long Run: Rank Gains vs. the IGE

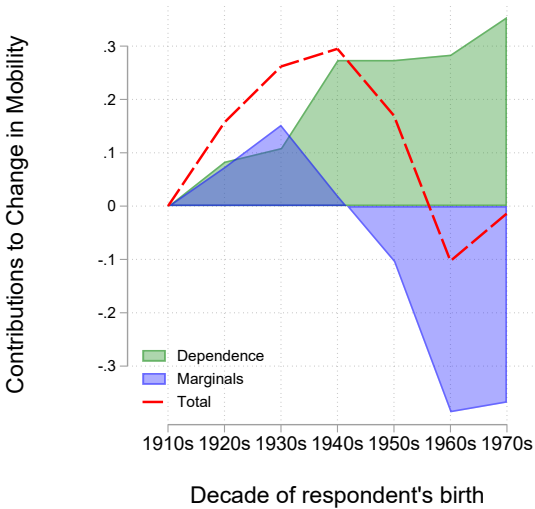

Other Measures

- **Dependence component:** rising mobility + plateau
  - Like the rank-rank slope
  - IGE and rank-rank still disagree for 1950s $\rightarrow$ 1960s
- **Marginal component:** child vs. parent dispersion pulls mobility down
  - $\frac{\sigma_K^{1960}/\sigma_P^{1960}}{\sigma_K^{1910}/\sigma_P^{1910}} \approx 1.75$

Long Run: Rank Gains vs. the IGE

Other Measures

- **Dependence component:** rising mobility + plateau
  - Like the rank-rank slope
  - IGE and rank-rank still disagree for 1950s $\rightarrow$ 1960s
- **Marginal component:** child vs. parent dispersion pulls mobility down
  - $\frac{\sigma_K^{1960}/\sigma_P^{1960}}{\sigma_K^{1910}/\sigma_P^{1910}} \approx 1.75$
- Dominates by 1960s $\longrightarrow$ post-1950 IGE mostly marginals

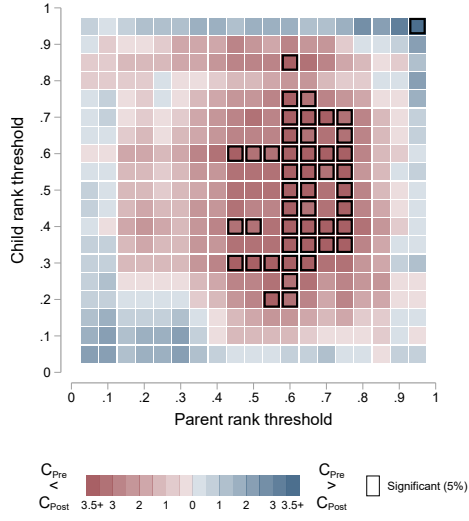

Mid-Century: Where the Copulas Cross

Conclusions

Implications For Applied Researchers

A single property—concordance—determines when standard mobility measures agree

Implications For Applied Researchers

A single property—concordance—determines when standard mobility measures agree

For applied researchers:

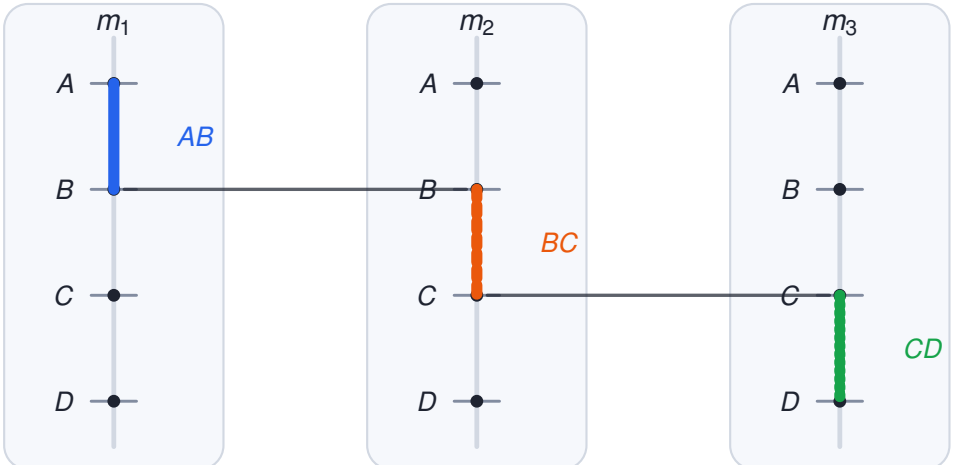

1. When concordance holds: measures are substitutes
   - Pick by data quality, not axiom: transitions for noisy data, IGE for clean panels, rank-rank for cross-country

2. When it fails: disagreement is informative, not noise
   - Agreement among a few measures $\neq$ robustness
   - Test it; locate it; report local rank-rank slopes & transition probabilities

3. Decomposition as diagnostic: rank-dependence vs. changing marginals

4. Policy: who gains, not how much $\longrightarrow$ effects across the full parental distribution

Chaining Measures

Gives full comparison of A, B, C and D in *any* measure

Details

Mass Points

Back

e.g. from bunching, top-coding, censoring, genuine discreteness $\longrightarrow$ no restrictions on F_K or F_P, but Copula 'indeterminate'

Solutions:

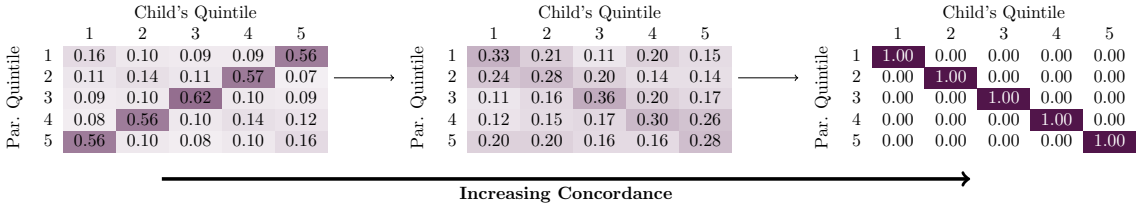

1. Parametric copulas
   - Does violence to discrete data
   - Restrictive

2. Carley (2002) bounds on copulas
   - A lot more math, but flexible
   - Worst-case bounds may not be tight

3. Pick an extension: checkerboard or Piecewise bilinear
   - Propositions 11, 13 in Genest and Nešlehová (2007) show the unique extension preserving concordance order of the original joint-distributions

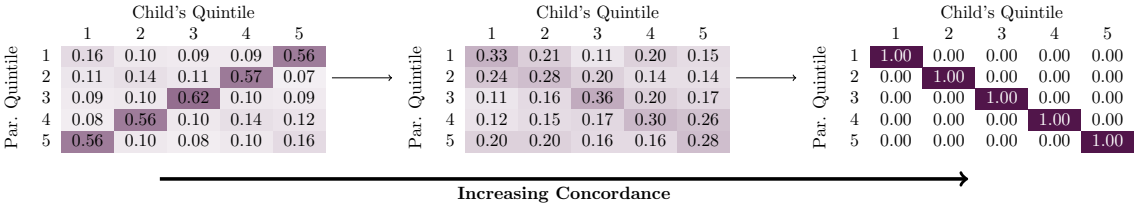

Concordance: Visual Intuition

Back

Concordance: Visual Intuition

Back

- Not just extreme cases

Assumption 1: Strong Diagonal Concentration

Back

Two results need more than concordance: mass must move toward the diagonal

1. Directional contraction: $\exists\, r^\star$ such that, for a.e. r and $s \geq 0$,

$$C^A_{K|P}(r+s \mid r) \geq C^B_{K|P}(r+s \mid r) \quad (r \leq r^\star), \qquad C^A_{K|P}(r-s \mid r) \leq C^B_{K|P}(r-s \mid r) \quad (r \geq r^\star)$$

   - Fewer large moves up from the bottom, down from the top $\longrightarrow$ Directional mobility

2. Diagonal interval dominance: for every rank interval $(a, b]$,

$$\Pr^A\Big(a < R^K \leq b,\ a < R^P \leq b\Big) \geq \Pr^B\Big(a < R^K \leq b,\ a < R^P \leq b\Big)$$

   - More parent-child pairs stay in the same interval $\longrightarrow$ Shorrocks trace

Both hold for Gaussian and FGM copulas as dependence rises. Pointwise (non-parametric) CER rotation instead needs $G(r) = \int_0^1 [C^A(u,r) - C^B(u,r)]\, du$ single-peaked at $r^\star$; the linear fit rotates around the median with no extra assumptions.

Why Does Concordance Order These Measures?

Back

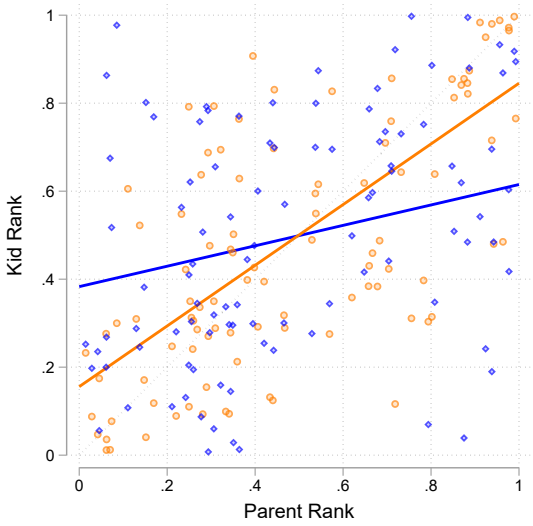

Rank-rank slope: an *average* of the copula

Why Does Concordance Order These Measures?

Back

Rank-rank slope: an *average* of the copula

Mobility Measure:

$$\rho = 12 \int\int \left[C(u,v) - uv \right] du\, dv$$

$C^A \geq C^B$ everywhere

$$\longrightarrow \int\int C^A \geq \int\int C^B$$

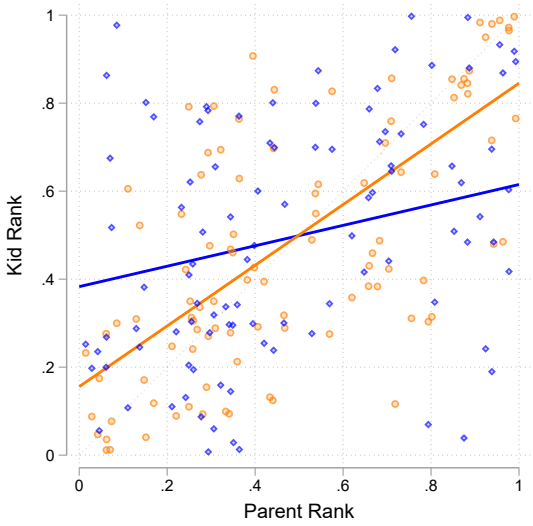

$$\longrightarrow \rho^A \geq \rho^B$$

(Lehmann 1966; Tchen 1980)

Why Does Concordance Order These Measures?

Back

Why Does Concordance Order These Measures? Illustration III

Back

Extension: Proxies & Measurement Error

Back

Prop 5: Observe proxy $E^g = H_g(R^g, \varepsilon^g)$ for generation g, H_g increasing, and ε independent of ranks. Let $\widetilde{C}$ denote copula for (E^K, E^P). Concordance ordering preserved:

$$C^A \succeq C^B \quad \longrightarrow \quad \widetilde{C}^A \succeq \widetilde{C}^B$$

Extension: Proxies & Measurement Error

Back

Prop 5: Observe proxy $E^g = H_g(R^g, \varepsilon^g)$ for generation g, H_g increasing, and ε independent of ranks. Let $\widetilde{C}$ denote copula for (E^K, E^P). Concordance ordering preserved:

$$C^A \succeq C^B \quad \longrightarrow \quad \widetilde{C}^A \succeq \widetilde{C}^B$$

$\longrightarrow$ Error may bias *levels* but ordering *preserved*

Extension: Proxies & Measurement Error

Back

Prop 5: Observe proxy $E^g = H_g(R^g, \varepsilon^g)$ for generation g, H_g increasing, and ε independent of ranks. Let $\widetilde{C}$ denote copula for (E^K, E^P). Concordance ordering preserved:

$$C^A \succeq C^B \quad \longrightarrow \quad \widetilde{C}^A \succeq \widetilde{C}^B$$

$\longrightarrow$ Error may bias *levels* but ordering *preserved*

- Covers common proxy cases

1. Education/occupation as income proxies: $Y \longrightarrow E$
2. Income and Education as skill proxies: $S \longrightarrow E, Y$

Extension: Proxies & Measurement Error

Back

Prop 5: Observe proxy $E^g = H_g(R^g, \varepsilon^g)$ for generation g, H_g increasing, and ε independent of ranks. Let $\widetilde{C}$ denote copula for (E^K, E^P). Concordance ordering preserved:

$$C^A \succeq C^B \quad \longrightarrow \quad \widetilde{C}^A \succeq \widetilde{C}^B$$

$\longrightarrow$ Error may bias *levels* but ordering *preserved*

- Covers common proxy cases
  1. Education/occupation as income proxies: $Y \longrightarrow E$
  2. Income and Education as skill proxies: $S \longrightarrow E, Y$
- Covers flexible measurement error cases $\widetilde{Y} = E = H_g(R^g, \varepsilon^g)$ (Corollary 1)
  1. (non-)Classical measurement error in (log-)incomes (Bound, Brown, Duncan & Rogers 1994)
  2. Measurement error in ranks (Chetverikov & Wilhelm 2023)
  3. Life cycle biases (Kitagawa, Nybom, & Stuhler 2018)

Proxies & Meas Error: Functional Forms

Back

Proxies:

1. Human capital determines incomes $Y = H(E) + \varepsilon$ with $E = H^{-1}(Y - \varepsilon)$
2. Ability determines education and income $E = H_E(S, \varepsilon)$ and $Y = H_Y(S, \varepsilon)$.

Proxies & Meas Error: Functional Forms

Back

Proxies:

1. Human capital determines incomes $Y = H(E) + \varepsilon$ with $E = H^{-1}(Y - \varepsilon)$

2. Ability determines education and income $E = H_E(S, \varepsilon)$ and $Y = H_Y(S, \varepsilon)$.

Measurement error:

1. Classical measurement error in incomes
   $\widetilde{Y}^K = F_K^{-1}(R^K) + \varepsilon^K, \qquad \widetilde{Y}^P = F_P^{-1}(R^P) + \varepsilon^P$

2. Measurement error in ranks
   $\widetilde{R}^K = F_{\widetilde{K}}\left(F_K^{-1}(R^K) + \varepsilon^K\right), \qquad \widetilde{R}^P = F_{\widetilde{P}}\left(F_P^{-1}(R^P) + \varepsilon^P\right)$

3. Life Cycle Biases
   $\widetilde{Y}^K = G_K\left(F_K^{-1}(R^K) + \mu_{\varepsilon^K} + \sigma_{\varepsilon^K}\varepsilon^K\right), \qquad \widetilde{Y}^P = G_P\left(F_P^{-1}(R^P) + \mu_{\varepsilon^P} + \sigma_{\varepsilon^P}\varepsilon^P\right)$

Measure specific weights

Back

- Measures expressed as

$$M_M = \int \int \phi_M \left(Y^K, Y^P \right) f \left(Y^K, Y^P \right) d\, Y^K d\, Y^P,$$

where $\phi_M \left(Y^K, Y^P \right)$: mobility-measure specific intensity

- For fixed marginals, any twice-differentiable measure: $M_M^A - M_M^B$

$$= \int_0^1 \int_0^1 W_M(R^K, R^P; F^K, F^P) \left[C^A(R^K, R^P) - C^B(R^K, R^P) \right] dR^K\, dR^P$$

where

$$W_M(R^K, R^P) = \frac{\phi_{M,12}\left(F_K^{-1}(R^K), F_P^{-1}(R^P)\right)}{f_K \left(F_K^{-1}(R^K) \right)\ f_P \left(F_P^{-1}(R^P) \right)}$$

- Works for non-continuous cases also

Jácome, Kuziemko & Naidu (2025) Replication

Testing The Concordance Order

Back

Set up as a moment inequality testing procedure (Andrews and Soares, 2010)

- Moments on a grid $\mathcal{G}$:

$$m_g \;=\; C_A(u_g, v_g) - C_B(u_g, v_g), \qquad g = 1, \ldots, G.$$

- Null hypothesis of dominance

$$H_0 :\; m_g \geq 0 \;\text{ for all } g = 1, \ldots, G \qquad \text{vs.} \qquad H_1 :\; m_g < 0 \;\text{ for some } g.$$

- Test statistic is the minimum of the studentized moments:

$$T_n \;=\; \min_{g=1,\ldots,G} \frac{\widehat{m}_g}{\widehat{s}_g},$$

  w/ bootstrap standard error $\widehat{s}_g$

- Test $A \succeq B$ and $B \succeq A$

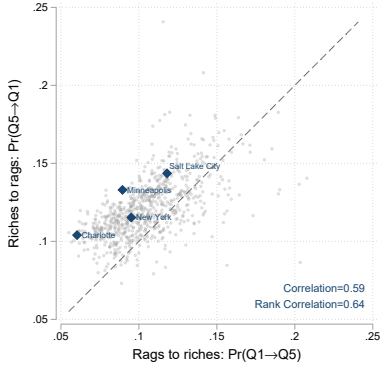

Spatial Mobility: Measure Disagreement Across CZs

Back

Chetty et al. (2014) CZ transition matrices, remapped to within-CZ copulas

Q1→Q1 vs. Q5→Q5 persistence

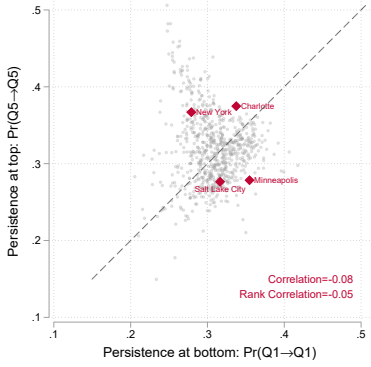

Q1→Q5 vs. Q5→Q1 tail mobility

- Salt Lake $\succ$ Charlotte on *every* measure...
  - ...but Salt Lake vs. NYC, NYC vs. Minneapolis: depends on measure
